Classes and Objects

Python is object oriented programming language
everything in python is an object with its properties and methods
Class is an object constructor/blueprint for creating objects
it defines attributes and behavior of the object

Creating a Class

```
# should be in CamelCase
class ClassName:
    code
```

Creating an Object

```
object_name = ClassName()
```

Class Constructor

```
class Person:
    # init constructor function
    def __init__(self, para1, para2):
    # self is self paramter attach to the class
        self.para1 = para1
p = Person("arg1", "arg2")
print(p.para1)
print(p.para2)

#OR
#CLASS WITH DEFAULT VALUE
class Person:
    def __init__(self, name="Jevon", age=18):
        self.name = name
        self.age = age
p = Person()
p.name = "Jevon"
```

Object Methods

```
class Person:
    def __init__(self, name):
        code
```

```
    def person_info(self):
        return f"Hi {self.name}"
```

Modify Class Default Values, add Parameter

```
class Person:
    def __init__(self, skills):
        self.skills = []
    def add_skills(self, skill):
        self.skills.append(skill)
```

Inheritance

```
reusing parent/superbase class code, all of its methods and properties
```

```
class Student(Person):
    pass

#OR
class Student(Person):
    def __init__(self, name)
        super().__init__(name) #access properties from the parent
```
